#### Abstract

The reaction of $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb})$ and $\mathrm{Cu}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ with the polydentate Schiff base ligand $\mathrm{OH}-\mathrm{C}_{10} \mathrm{H}_{7}-\mathrm{CH}=\mathrm{NC}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)\left(\mathrm{CH}_{2} \mathrm{OH}\right)_{2}\left(\mathrm{H}_{3} \mathrm{~L}\right)$ in $\mathrm{Me}_{2} \mathrm{CO}$ afforded the heptanuclear heterometallic complexes $\left[\mathrm{Cu}_{5} \mathrm{Ln}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right](\mathrm{Ln}=\mathrm{Gd}(\mathbf{1}), \mathrm{Tb}(\mathbf{2}))$ which were characterized by single-crystal X-ray crystallography (1) and powder XRD measurements (2). Both complexes are isomorphous and consist of a central core $\left\{\mathrm{Cu}_{5}^{\text {II }} \mathrm{Ln}_{2}^{\text {III }}\left(\mu_{3}-\mathrm{OR}\right)_{6}\left(\mu_{3}-\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\right\}^{8+}$ described as two distorted centrosymmetrically related cubane subunits, $\left\{\mathrm{Cu}_{3}^{\mathrm{II}} \mathrm{Ln}^{\text {III }}\left(\mu_{3}-\mathrm{OR}\right)_{3}\left(\mu_{3}-\mathrm{O}_{2} \mathrm{CMe}\right)\right\}^{5+}$, with the common apex, $\mathrm{Cu}(1)$, residing on an inversion center. Peripheral ligation and bridging is provided by two triply and two doubly deprotonated Schiff base ligands, two $\mu_{3}$-acetates and four chelate nitrates. Magnetic susceptibility measurements revealed the presence of dominant ferromagnetic interactions for both complexes. The magnetocaloric effect of $\mathbf{1}$ was examined via isothermal magnetization measurements under various applied fields and the maximum entropy change was found equal to $15.7 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ at 2 K for $\Delta H=5 \mathrm{~T}$. Ac susceptibility measurements of 2 revealed slow magnetic relaxation process suggesting the presence of single-molecule magnet behavior.

## 1. Introduction

Molecular magnetic materials with interesting structures and noteworthy physical properties have been extensively studied over the past decades, and have been proposed for potential applications in high-density information storage devices, quantum computing, spintronics and magnetic refrigeration [1]. The useful physical property of each material, depends on the potential application. For example, molecular magnetic materials should exhibit large energy barrier for magnetization reversal in order to find potential applications as information storage media. The combination of 3d/4f metal ions in one molecule can result in high spin ground states (via the involvement of the 3d metal ions) along with large single-ion anisotropy (via the presence of the 4 f metal ions) and provides, in many cases, considerable energy barriers for magnetization reversal leading to single-molecule magnet (SMM) behavior. On the contrary, magnetic refrigeration requires molecules possessing a large spin ground state and negligible magnetic anisotropy. The magnetic refrigeration is based on the magnetocaloric effect (MCE) i.e. the isothermal change of magnetic entropy ( $\Delta S_{\mathrm{m}}$ ) and adiabatic change of temperature ( $\Delta T_{\mathrm{ad}}$ ) that

[^0]follow a change of the applied magnetic field $(\Delta H)$.The refrigeration cycle involves (i) the adiabatic magnetization of the sample, i.e. the increase of the external magnetic field followed by the decrease of the magnetic entropy and heat capacity and increase of the temperature, (ii) the isomagnetic enthalpic transfer, i.e. the removal of the added heat from the sample under constant magnetic field, (iii) the adiabatic demagnetization of the sample, i.e. the decrease of the external magnetic field followed by cooling of the sample because the magnetic entropy remains constant, and (iv) the isomagnetic entropic transfer, i.e. the sample is cooler than the environment therefore it is heated again in order for a new cycle to begin. The upper limit for the entropy change at $T=\infty$ is $\Delta S_{\mathrm{m}}=R \ln (2 S+1)$, where $R$ is the gas constant and $S$ is the spin value. In order to exhibit large MCE with potential applications as low-temperature magnetic refrigerants, the molecular magnetic materials should combine a large spin ground state, negligible magnetic anisotropy, considerable degeneracy via low-lying excited states, large metal-to-ligand ratio and low molecular weight. Molecules with high spin ground state and large anisotropy, such as $\mathrm{Mn}_{12}$ and $\mathrm{Fe}_{8}$, have been initially examined as potential magnetic refrigerants in the liquid helium regime, albeit the fact that the magnetic anisotropy reduces the maxima of the magnetic entropy due to degeneracy lifting of the energy levels [2]. The use of the isotropic $\mathrm{Gd}^{\text {III }}(\mathrm{S}=7 / 2)$ ion has contributed in both
research fields, i.e. single-molecule magnets and magnetic refrigerants. Gd-based complexes and multi-dimensional coordination polymers have been extensively studied as magnetic refrigerants with entropy change $-\Delta S_{\mathrm{m}}$ up to $59 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ (at 3 K and $\Delta H=$ 7 T) [3-8].

The synthesis of heterometallic 3d/4f complexes is mainly based on the hard and soft acids and bases (HSAB) principle according to which, ligands possessing different donor atoms suitable for coordination to 3 d and 4 f metal ions, preferably nitrogen and oxygen, respectively, are used. Suitable co-ligands may also be present in order to assist the self-assembly processes. In general, the mixing of 3 d and 4 f ions with organic ligands would produce pure 3d or 4 f complexes rather than heterometallic $3 \mathrm{~d} / 4 \mathrm{f}$ ones. The final products of the reactions depend on their relative potential energy and based on HSAB rules it is assumed that the use of suitably designed organic ligands which contain one or more coordination pockets of both nitrogen and oxygen donors would favor the synthesis of 3d/4f heterometallic complexes. Among the ligands used, Schiff bases have been widely used for the synthesis of 3d, 4f and $3 \mathrm{~d} / 4 \mathrm{f}$ complexes because they offer the advantage of modular synthesis via various combinations of starting materials and in addition they can be easily functionalized by choosing starting materials with the desired side groups [9-12]. The various Schiff base ligands containing coordination pockets as well as hydroxyl, amino and carboxylate groups have resulted in a large number of $3 \mathrm{~d} / 4 \mathrm{f}$ complexes [13-22]. Among them, $\mathrm{Cu}^{\mathrm{II}}-\mathrm{Ln}^{\mathrm{III}}$ Schiff base complexes have been extensively studied, for example dinuclear [23], trinuclear [24-27], tetranuclear [28-31] and higher nuclearity clusters [17,32-34]. Neighboring $\operatorname{Ln}^{\text {III }}$ ions exhibit similar ionic radius and coordinating features, leading to isomorphic complexes of the whole $4 f$ series, whose magnetic properties are governed by the nature of the $f$ orbitals. The significant magnetic anisotropy of $\mathrm{Tb}^{\text {III }}, \mathrm{Dy}^{\text {IIII }}, \mathrm{Ho}^{\text {III }}$ and $\mathrm{Er}^{\text {IIII }}$, as a result of the large spin-orbital coupling as well as the crystal-field effect, make these ions excellent candidates for the synthesis of molecular nanomagnets, whereas the isotropic $\mathrm{Gd}^{\text {III }}$ ion is more suitable for magnetocaloric measurements and more importantly as a model ion for theoretical calculations concerning exchange interactions within $3 \mathrm{~d} / 4 \mathrm{f}$ clusters.

We present herein a part of our work on the $\mathrm{Cu}^{\mathrm{II}} / \mathrm{Ln}^{\mathrm{III}}$ chemistry with Schiff base ligands based on 2-hydroxy-1-naphthaldehyde and various amino-alcohols as a means to new molecular magnetic materials, i.e. the synthesis and magnetic study of the heptanuclear clusters $\left[\mathrm{Cu}_{5} \mathrm{Ln}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right](\mathrm{Ln}=\mathrm{Gd}(\mathbf{1})$, $\mathrm{Tb}(\mathbf{2})$, and $\left.\mathrm{H}_{3} \mathrm{~L}=\mathrm{OH}-\mathrm{C}_{10} \mathrm{H}_{7}-\mathrm{CH}=\mathrm{NC}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)\left(\mathrm{CH}_{2} \mathrm{OH}\right)_{2}\right)$.

## 2. Experimental

### 2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co). All chemicals and solvents were of reagent grade. The ligand $\mathrm{OH}-\mathrm{C}_{10} \mathrm{H}_{7}-\mathrm{CH}=\mathrm{NC}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)\left(\mathrm{CH}_{2}-\right.$ $\mathrm{OH})_{2}, \mathrm{H}_{3} \mathrm{~L}$ was synthesized by the equimolar reaction of 2 -hydroxy-1-naphthaldehyde and 2-amino-2-ethyl-1,3-propanediol in MeOH . The immediately formed yellow solution was refluxed for 1 h and concentrated in rotary evaporator to obtain yellow crystals of $\mathrm{H}_{3} \mathrm{~L}$. Elemental analysis for carbon, hydrogen, and nitrogen was performed on a Perkin Elmer 2400/II automatic analyzer. Infrared spectra were recorded as KBr pellets in the range 4000$400 \mathrm{~cm}^{-1}$ on a Bruker Equinox $55 / \mathrm{S}$ FT-IR spectrophotometer. Vari-able-temperature and field magnetic measurements were carried out on polycrystalline samples using Quantum Design PPMS 9T and SQUID magnetometer Quantum Design MPMS 5.5. Diamagnetic corrections were estimated from Pascal's constants.

### 2.2. Compound preparations

### 2.2.1. $\left[\mathrm{Cu}_{5} \mathrm{Gd}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right] \cdot 4 \mathrm{Me}_{2} \mathrm{CO}\left(1.4 \mathrm{Me}_{2} \mathrm{CO}\right)$

Solid $\mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(0.075 \mathrm{mmol}, 0.0339 \mathrm{~g})$ was added under stirring to a yellow solution of $\mathrm{H}_{3} \mathrm{~L}(0.10 \mathrm{mmol}, 0.0273 \mathrm{~g})$ in $\mathrm{Me}_{2} \mathrm{CO}$ ( 15 mL ). After 10 min of stirring, solid $\mathrm{Cu}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}(0.10 \mathrm{mmol}$, 0.0200 g ) was added and the solution became dark green. The stirring continued for 30 min and the final reaction solution was kept in closed vials. Crystals of $\mathbf{1}$ were formed after three days. Yield: $0.0095 \mathrm{~g}, \sim 20 \%$ based on $\mathrm{Cu}^{\text {II }} . \mathrm{C}_{80} \mathrm{H}_{96} \mathrm{~N}_{8} \mathrm{O}_{32} \mathrm{Cu}_{5} \mathrm{Gd}_{2}$ (f.w. $=2313.84$ ) requires C, 41.52; H, 4.18; N, 4.84\%. Found: C, 41.39; H, 4.15; N, 4.82\%. FT-IR ( KBr pellets, $\mathrm{cm}^{-1}$ ): 3376(br), 3058(w), 2964(m), 2924(m), 1703(m), 1688(m), 1620(vs), 1605(vs), 1585(s), 1583(s), 1538(s), 1506(s), 1454(s), 1429(s), 1381(vs), 1362(s), 1336(s), 1292(s), 1275(sh), 1250(m), 1218(w), 1188(s), 1160(s), 1140(s), 1119(m), 1088(m), 1065(m), 1032(s), 998(m), 972(w), 948(m), 935(w), 912(m), 859(m), 830(s), 816(m), 780(m), 745(s), 659(w), 645(s), 575(s), 528(w), 514(w), 488(m), 463(m), 450(m), 415(m).

### 2.2.2. $\left[\mathrm{Cu}_{5} \mathrm{~Tb}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right] \cdot 4 \mathrm{Me}_{2} \mathrm{CO}\left(2 \cdot 4 \mathrm{Me}_{2} \mathrm{CO}\right)$

Solid $\mathrm{Tb}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(0.075 \mathrm{mmol}, 0.0340 \mathrm{~g})$ was added under stirring to a yellow solution of $\mathrm{H}_{3} \mathrm{~L}(0.075 \mathrm{mmol}, 0.0205 \mathrm{~g})$ in $\mathrm{Me}_{2^{-}}$ $\mathrm{CO}(5 \mathrm{~mL})$. After 10 min of stirring, solid $\mathrm{Cu}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}(0.075$ $\mathrm{mmol}, 0.0150 \mathrm{~g})$ was added and the solution became dark green. The stirring continued for 30 min and the final reaction solution was kept in closed vials. Microcrystalline $\mathbf{2}$ was formed after five days. The identity of the microcrystalline material was established by powder XRD measurements (see Fig. S1). Yield: 0.0219 g, ~60\% based on $\mathrm{Cu}^{\text {II. }} \mathrm{C}_{80} \mathrm{H}_{96} \mathrm{~N}_{8} \mathrm{O}_{32} \mathrm{Cu}_{5} \mathrm{~Tb}_{2}($ f.w. $=2317.26$ ) requires C , 41.47; H, 4.18; N, 4.84\%. Found: C, 41.37; H, 4.16; N, 4.82\%. FT-IR ( KBr pellets, $\mathrm{cm}^{-1}$ ): 3378(br), 3058(w), 2965(m), 2924(m), 1704 (m), 1689(m), 1620(vs), 1604(vs), 1586(s), 1583(s), 1538(s), 1505 (s), 1454(s), 1428(s), 1381(vs), 1362(s), 1337(s), 1292(s), 1276 (sh), 1250(m), 1219(w), 1188(s), 1161(s), 1140(s), 1119(m), 1089 (m), 1065(m), 1032(s), 998(m), 970(w), 948(m), 936(w), 912(m), 858(m), 830(s), 817(m), 780(m), 746(s), 659(w), 645(s), 576(s), 528(w), 514(w), 487(m), 463(m), 451(m), 414(m).

### 2.3. Single crystal X-ray crystallography

Crystals of $\mathbf{1} 4 \mathrm{Me}_{2} \mathrm{CO}(0.12 \times 0.15 \times 0.30 \mathrm{~mm})$ were taken from the mother liquor and immediately cooled to $-103^{\circ} \mathrm{C}$. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Mo $\mathrm{K} \alpha$ radiation. Data collection ( $\omega$-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CrystalClear program package [35]. The structure was solved by direct methods using shelxs-97 and refined by full-matrix least-squares techniques on $F^{2}$ with sheLxL ver2014/6 [36]. Important crystallographic and refinement data are listed in Table 1. Further experimental crystallographic details for $1.4 \mathrm{Me}_{2} \mathrm{CO}: 2 \theta_{\max }=54^{\circ}$; reflections collected/unique/used, 53464/9632 $\left[R_{\text {int }}=0.0283\right] /$ 9632; 742 parameters refined; $(\Delta / \sigma)_{\max }=0.002 ;(\Delta \rho)_{\text {max }} /(\Delta \rho)_{\text {min }}$ $=0.497 /-0.381 \mathrm{e} / \AA^{3} ; R 1 / \mathrm{wR2}$ (for all data), $0.0447 / 0.0220$. Hydrogen atoms were either located by difference maps and were refined isotropically or were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically. Plots of the structures were drawn using the Diamond 3 program package [37].

## 3. Results and discussion

### 3.1. Synthesis and spectroscopic characterization

The reaction between $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot x \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb})$ and $\mathrm{Cu}\left(\mathrm{O}_{2^{-}}\right.$ $\mathrm{CMe})_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ with the Schiff base ligand $\mathrm{H}_{3} \mathrm{~L}$ in $\mathrm{Me}_{2} \mathrm{CO}$ under stirring

at room temperature afforded dark green solutions which gave green crystals (1) or green microcrystalline materials (2) from closed vials, according to the reaction:

$$
\begin{align*}
& 2 \mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}+5 \mathrm{Cu}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}+4 \mathrm{H}_{3} \mathrm{~L} \xrightarrow{\mathrm{Me}_{2} \mathrm{CO}} \\
& \quad \times\left[\mathrm{Cu}_{5} \mathrm{Ln}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right]_{\mathbf{1 - 2}}+2 \mathrm{HNO}_{3}+8 \mathrm{MeCO}_{2} \mathrm{H}+17 \mathrm{H}_{2} \mathrm{O} \tag{1}
\end{align*}
$$

The above reaction performed in different solvents (MeOH, MeCN etc) and also similar reactions involving other copper salts, e.g. chlorides, nitrates, perchlorates, gave microcrystalline or oily products which could not be identified.

The IR spectrum of $\mathbf{1 - 2}$ exhibits a broad band a $3378 \mathrm{~cm}^{-1}$ attributed to the $v(\mathrm{OH})$ vibrations due to the presence of the alkoxo groups of the $\mathrm{HL}^{-}$ligands. The bands at 3060,2960 and $2920 \mathrm{~cm}^{-1}$ are attributed to the $v(=\mathrm{CH}), v\left(\mathrm{CH}_{3}\right)$ and $v\left(\mathrm{CH}_{2}\right)$ stretching vibrations of the Schiff base and acetate ligands. A set of peaks in the $1600-1400 \mathrm{~cm}^{-1}$ region are attributed to the stretching vibrations of the $\alpha$-substituted naphthalene ring and the strong band at $\sim 745$ $\mathrm{cm}^{-1}$ is attributed to the out-of-plane CH deformation vibrations of the naphthalene ring. The very strong band at $\sim 1605 \mathrm{~cm}^{-1}$ is due to $v(\mathrm{C}=\mathrm{N})$ vibration of the Schiff base ligands. This band appears at lower frequency with respect to $\mathrm{H}_{3} \mathrm{~L}\left(1620 \mathrm{~cm}^{-1}\right)$ suggesting coordination of the metal ions through the imino nitrogen. The $v$ ( $\mathrm{C}-\mathrm{O}$ ) stretching frequency of the phenolic oxygen of $\mathrm{H}_{3} \mathrm{~L}$ is seen at $1396 \mathrm{~cm}^{-1}$ and shifts to $\sim 1355 \mathrm{~cm}^{-1}$ indicating coordination to the metal ions [38]. The medium intensity bands at $\sim 1703$ $\mathrm{cm}^{-1}$ are attributed to the $v(\mathrm{C}=\mathrm{O})$ vibration of the solvate $\mathrm{Me}_{2} \mathrm{CO}$ molecules. The strong absorption bands at 1250 and $1360 \mathrm{~cm}^{-1}$ are attributed to the symmetric and antisymmetric vibrations of the coordinated nitrates [39]. The $v_{\mathrm{as}}(\mathrm{C}=\mathrm{O})$ and $v_{\mathrm{s}}(\mathrm{C}=\mathrm{O})$ are observed at $\sim 1505$ and $\sim 1362 \mathrm{~cm}^{-1}$, respectively, with $\Delta \sim 143$ $\mathrm{cm}^{-1}$ as expected for the bridging mode of the acetate ligands. The strong band at $\sim 1380 \mathrm{~cm}^{-1}$ is attributed to the presence of $v_{3}\left(E^{\prime}\right)\left[v_{\mathrm{d}}(\mathrm{NO})\right]$ mode of uncoordinated $D_{3 h}$ ionic nitrates; their presence is probably due to partial substitution of coordinated nitrates from bromides during the preparation of the KBr pellet under pressure [40].

### 3.2. Description of the structure

Complex1 crystallizes in the monoclinic space group $P 2_{1} / c$; complex 2 is isomorphous to $\mathbf{1}$ based on powder XRD data (Fig. S1). The asymmetric unit of $\mathbf{1}$ contains half of the complex and two acetone solvates. The complex is neutral and consists of

Fig. 1. Partially labeled plot of 1 .The metal core is highlighted in black. Color code: Gd pink octant, Cu green octant, O red, N blue, C light grey. Primed atoms are generated by symmetry: (') $-x, 1-y, 2-z$. (Colour online.)
five $\mathrm{Cu}^{\text {II }}$ and two $\mathrm{Gd}^{\text {III }}$ ions which are held together via six $\mu_{3}$ $\mathrm{O}_{\text {alkoxo }}$ and two $\mu_{3}-\mathrm{O}_{\text {acetato }}$ atoms. The topology of the central core, $\left\{\mathrm{Cu}_{5}^{\mathrm{II}} \mathrm{Gd}_{2}^{\mathrm{III}}\left(\mu_{3}-\mathrm{OR}\right)_{6}\left(\mu_{3}-\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\right\}^{8+}$, is described as two distorted cubane subunits, $\left\{\mathrm{Cu}_{3}^{\mathrm{II}} \mathrm{Gd}^{\text {III }}\left(\mu_{3}-\mathrm{OR}\right)_{3}\left(\mu_{3}-\mathrm{O}_{2} \mathrm{CMe}\right)\right\}^{5+}$, with a common apex on $\mathrm{Cu}(1)$ which resides on an inversion center. The molecular structure of the heptanuclear complex $\left[\mathrm{Cu}_{5} \mathrm{Gd}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(-\right.$ $\mathrm{HL})_{2}$ ( $\mathbf{1}$ ) is shown in Fig. 1. Selected bond distances and angles are listed in Table 2.

The seven metal ions are held together via two $\mathrm{L}^{3-}$ and two $\mathrm{HL}^{2-}$ ligands and two $\mu_{3}-\kappa^{3} \mathrm{O}: \kappa^{\prime} \mathrm{MeCO}_{2}^{-}$ligands. The triply deprotonated ligands, $\mathrm{L}^{3-}$, behave as $\mu_{5}-\mathrm{K}^{3} 0, \kappa^{3} \mathrm{O}^{\prime}, \kappa \mathrm{K}^{\prime \prime}, \kappa N$ (Scheme 1) and bridge atoms $\mathrm{Cu}(1) / \mathrm{Cu}(3) / \mathrm{Gd}(1)$ of one cubane subunit with atoms $\mathrm{Cu}\left(2^{\prime}\right) / \mathrm{Gd}\left(1^{\prime}\right)$ of its centrosymmetric congener. The $\mathrm{L}^{3-}$ ligand (defined by atoms $\mathrm{O}(11) / \mathrm{N}(11) / \mathrm{O}(12) / \mathrm{O}(13)$ ) chelates around Cu (3) through the $\mathrm{O}_{\text {phenoxo }}(\mathrm{O}(11)), \mathrm{N}_{\text {imino }}(\mathrm{N}(11))$ and $\mathrm{O}_{\text {alkoxo }}(\mathrm{O}$ (12)) atoms; the latter is also coordinated to $\mathrm{Gd}(1)$ and $\mathrm{Cu}(1)$, thus acting as $\mu_{3}$-bridge. The second deprotonated $\mathrm{O}_{\text {alkoxo }}(\mathrm{O}(13))$ of $\mathrm{L}^{3-}$ ligand coordinates to $\mathrm{Cu}(1)$ and also to the centrosymmetric $\mathrm{Cu}\left(2^{\prime}\right)$

Symmetry operation: (') $-x, 1-y, 2-z$.
and $\operatorname{Gd}\left(1^{\prime}\right)$, acting also as $\mu_{3}$-bridge. The doubly deprotonated ligands, $\mathrm{HL}^{2-}$, behave as $\mu_{3}-\kappa^{3} O, \kappa O^{\prime}, \kappa O^{\prime \prime}, \kappa N$ (Scheme 1) between atoms $\mathrm{Cu}(2) / \mathrm{Cu}(3) / \mathrm{Gd}(1)$ of each cubane subunit. The $\mathrm{HL}^{2-}$ ligand (defined by $\mathrm{O}(1) / \mathrm{N}(1) / \mathrm{O}(2) / \mathrm{O}(3))$ chelates around $\mathrm{Cu}(2)$ through the $\mathrm{O}_{\text {phenoxo }}(\mathrm{O}(1)), \mathrm{N}_{\text {imino }}(\mathrm{N}(1))$ and $\mathrm{O}_{\text {alkoxo }}(\mathrm{O}(2))$ atoms; the latter is also coordinated to $\mathrm{Gd}(1)$ and $\mathrm{Cu}(3)$, thus acting as $\mu_{3}$-bridge. The protonated $\mathrm{O}_{\text {alkoxo }}, \mathrm{O}(3)$, is coordinated to $\mathrm{Gd}(1)$.
$\mathrm{Cu}(1)$ presents distorted octahedral coordination geometry consisting of two deprotonated $\mathrm{O}_{\text {alkoxo }}$ atoms from two $\mathrm{L}^{3-}$ ligands ( O (12)/O(13) and their centrosymmetric ones) with $\mathrm{Cu}(1)-\mathrm{O}_{\text {alkoxo }}$ $\sim 1.95$ and $1.99 \AA$ in the equatorial plane, and two $\mu_{3}$-acetato oxygen atoms $\left(\mathrm{O}(41) / \mathrm{O}\left(41^{\prime}\right)\right)$ in the apical positions with $\mathrm{Cu}(1)-\mathrm{O}_{\text {acetato }}$ $\sim 2.46 \AA \AA . \mathrm{Cu}(2)$ and $\mathrm{Cu}(3)$ and their centrosymmetric ones are fivecoordinate with square pyramidal geometry. The equatorial plane in $\mathrm{Cu}(2)$ is defined by atoms $\mathrm{O}(1) / \mathrm{N}(1) / \mathrm{O}(2)$ of one $\mathrm{HL}^{2-}$ and O ( $41^{\prime}$ ) of one $\mu_{3}-\mathrm{O}_{\text {acetate }}$ with bond distances in the range 1.88 $2.02 \AA$ and the apical position is occupied by $\mathrm{O}\left(13^{\prime}\right)$ of one $\mathrm{L}^{3-}$ at $\sim 2.88 \AA$. The trigonality index $\tau=0.02$ indicates almost ideal square pyramidal geometry in $\mathrm{Cu}(2)$. The equatorial plane in Cu (3) is defined by atoms $\mathrm{O}(11) / \mathrm{N}(11) / \mathrm{O}(12)$ of one $\mathrm{L}^{3-}$ and $\mathrm{O}(2)$, one of $\mu_{3}-\mathrm{O}_{\text {alkoxo }}$ atoms of $\mathrm{HL}^{2-}$ with bond distances in the range $1.88-1.97 \AA$ and the apical position is occupied by the $\mu_{3}-\mathrm{O}_{\text {acetato }}$ atom $\mathrm{O}\left(41^{\prime}\right)$ at $\sim 2.49 \AA$. The trigonality index $\tau=0.16$ suggests square pyramidal geometry in $\mathrm{Cu}(3)$. The coordination sphere around $\mathrm{Gd}^{\mathrm{III}}$ ions consists of nine oxygen atoms, the $\mu_{3}-\mathrm{O}_{\text {alkoxo }} \mathrm{O}$ (2) and the protonated $\mathrm{O}_{\text {alkoxo }} \mathrm{O}(3)$ of $\mathrm{HL}^{2-}$, the two $\mu_{3}-\mathrm{O}_{\text {alkoxo }} \mathrm{O}$ (12) and $\mathrm{O}(13)$ of $\mathrm{L}^{3-}$, the monodentate $\mathrm{O}_{\text {acetato }} \mathrm{O}(42)$ and atoms $\mathrm{O}(21) / \mathrm{O}(22)$ and $\mathrm{O}(31) / \mathrm{O}(32)$ from two chelate $\mathrm{NO}_{3}^{-}$ions. The bond distances around the gadolinium ions are in the range 2.282(1)$2.565(1) \AA$. Continuous Shape Measures by using the program SHAPE [41] show that the best-fit polyhedron around the $\operatorname{Gd}(1)$ atoms in $\mathbf{1}$ is either a spherical capped square antiprism CSAPR-9 ( $\mathrm{CShM}=1.31428$ ) or a muffin MFF-9 $(\mathrm{CShM}=1.31490)$.

The protonated alkoxo group of each $\mathrm{HL}^{2-}$ participates in hydrogen bond with one of the $\mathrm{Me}_{2} \mathrm{CO}$ solvate molecules $[\mathrm{O}(3) \ldots$ $\mathrm{O}(51)=2.676 \AA(-x, 0.5+y, 1.5-z), \mathrm{HO}(3) \cdots \mathrm{O}(51)=1.989 \AA, \mathrm{O}$ (3) $-\mathrm{HO}(3) \cdots \mathrm{O}(51)=166.3^{\circ}$; Fig. S2].

### 3.3. Magnetic measurements

Magnetic susceptibility measurements as a function of temperature were recorded from polycrystalline samples of 1-2 at 1000 Oe dc field. The $\chi_{\mathrm{M}} T$ product for $\mathbf{1}$ at 300 K is $15.16 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ which is lower than the theoretical value of $17.625 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ for five $\mathrm{Cu}^{\mathrm{II}}$ ions ( $S=1 / 2$ with $C=0.375 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}, g=2$ ) and two $\mathrm{Gd}^{\text {III }}$ ions ( $S=7 / 2$ with $C=7.875 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}, g=2$ ). The $\chi_{\mathrm{M}} T$ product increases gradually as the temperature is decreasing reaching the value of $18.06 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ at 15 K and then it increases rapidly to the value of $24.27 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ at 2 K (Fig. 2). The overall temperature dependence of the $\chi_{\mathrm{M}} T$ product suggests

$\mu_{5}-\kappa^{3} O: \kappa^{3} O^{\prime}: \kappa O^{\prime \prime}: \kappa N$

$\mu_{3}-\kappa^{3} О: \kappa O^{\prime}: \kappa O^{\prime \prime}: \kappa N$

Scheme 1. The coordination modes of the $\mathrm{L}^{3-}$ and $\mathrm{HL}^{2-}$ ligands in $\mathbf{1}$.

Fig. 2. $\chi_{\mathrm{M}} T$ vs. $T$ plots for 1 and 2 at 1000 Oe.

Fig. 3. Magnetization curves for $\mathbf{1}$ and $\mathbf{2}$ at 2 K .
the presence of dominant ferromagnetic interactions between the five $\mathrm{Cu}^{\text {II }}$ and the two $\mathrm{Gd}^{\text {III }}$ ions. The magnetization measurements at 2 K as a function of the external applied field show a rapid increase upon increasing of the magnetic field reaching a value of $16.12 \mathrm{~N} \mu_{\mathrm{B}}$ at 8 T (Fig. 3). The clear saturation above 4 T suggests the presence of an isolated ground state of low magnetic anisotropy. The saturation of $M$ at $16.12 \mu_{\mathrm{B}}$ is lower than the value of $19 \mu_{\mathrm{B}}$ expected for two $\mathrm{Gd}^{\text {III }}(S=7 / 2)$ ions and five $\mathrm{Cu}^{\text {II }}(S=1 / 2)$ ions which are uncoupled or completely ferromagnetically coupled ( $S_{T}=19 / 2$ ), suggesting that some of the metal ions are antiferromagnetically coupled. This can be achieved if we assume that the central $\mathrm{Cu}^{\mathrm{II}}$ ion has opposite spin arrangement with respect to the other metal ions, leading to a total ground spin state of $S=$ $17 / 2$. The saturation value of the magnetization should be then equal to $17 \mu_{\mathrm{B}}$ which is close to the experimental value of $16.12 \mu_{\mathrm{B}}$.

Magnetization data were recorded in the $2-9 \mathrm{~K}$ temperature range under external applied magnetic field up to 5 T in order to explore the magnetic entropy changes $-\Delta S_{\mathrm{m}}$ and evaluate the magnetocaloric effect (MCE) of 1. Field-dependent magnetization plots for $\mathbf{1}$ are shown in Fig. 4. The $-\Delta S_{\mathrm{m}}$ can be calculated from the experimental magnetization data by using the Maxwell equation

Fig. 4. Field-dependent magnetization plots for $\mathbf{1}$ at $2-9 \mathrm{~K}$.

(b)

Fig. 5. The temperature dependent magnetic entropy change for $\mathbf{1}$.
$-\Delta S_{m}(T)_{\Delta H}=\int[\vartheta M(T, H) / \vartheta T]_{H} \mathrm{~d} H$
or by using the simpler numerical approximation to the above integral [42]
$\left|\Delta S_{m}\right|=\sum_{\mathrm{i}} \frac{M_{i}-M_{1+1}}{T_{i}-T_{1+1}} \Delta H_{i}$
where $M_{\mathrm{i}}$ and $M_{\mathrm{i}+1}$ are the experimental values of magnetization at $T_{\mathrm{i}}$ and $T_{\mathrm{i}+1}$ temperatures, respectively, under an applied field of intensity $H_{\mathrm{i}}$. The experimental values of the magnetic entropy change obtained from the experimental isothermal magnetization curves under various magnetic field variations are shown in Fig. 5. The maximum entropy change of $15.7 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ is obtained at 2 K for $\Delta H=5 \mathrm{~T}$. For a system containing two $\mathrm{Gd}^{\text {III }}(S=7 / 2)$ and five $\mathrm{Cu}^{\text {II }}(S=1 / 2)$ ions which are fully decoupled, the maximum $-\Delta S_{\mathrm{m}}$ value of $27.4 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ can be calculated from the equation $-\Delta S_{\mathrm{m}}$ $=n R \ln (2 S+1)$, which is larger than the value calculated experimentally by isothermal magnetization measurements. The maximum entropy change obtained in several Cu-Gd complexes of various
nuclearities and metal topologies are in the range $11.9-34.5 \mathrm{~J} \mathrm{~kg}^{-1}$ $\mathrm{K}^{-1}$ in the temperature range $2.0-4.5 \mathrm{~K}$ for $\Delta H=7 \mathrm{~T}$ [43-47].

The $\chi_{\mathrm{M}} T$ product for 2 at 300 K is $26.32 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ which is slightly larger than the theoretical value of $25.50 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ for five $\mathrm{Cu}^{\text {II }}$ ions ( $S=1 / 2$ with $C=0.375 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}, g=2$ ) and two $\mathrm{Tb}^{\mathrm{III}}$ ions ( $S=3, L=3, J=6$ with $C=11.81 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}, g=3 / 2$ ). The $\chi_{\mathrm{m}} T$ product increases gradually upon lowering the temperature and reaches the value of $77.36 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ at 4 K and then drops to $64.95 \mathrm{~cm}^{3} \mathrm{Kmol}^{-1}$ at 2 K (Fig. 2). The overall temperature dependence of the $\chi_{\mathrm{m}} T$ product suggests the presence of dominant ferromagnetic interactions between the five $\mathrm{Cu}^{\text {II }}$ and the two $\mathrm{Tb}^{\text {III }}$ ions. The large value of $\chi_{\mathrm{M}} T$ product at 2 K suggests the presence of a large spin ground state. The magnetization measurements at 2 K as a function of the external applied field show a rapid increase upon increasing of the magnetic field reaching a value of $18.28 \mathrm{~N} \mu_{\mathrm{B}}$ at 8 T (Fig. 3) without saturation. The value of the magnetization is lower than the value of $23 \mu_{\mathrm{B}}$ expected for two $\mathrm{Tb}^{\text {III }}(J=6, g=3 / 2)$ ions and five $\mathrm{Cu}^{\text {II }}(S=1 / 2, g=2)$ ions which are uncoupled or completely ferromagnetically coupled. This behavior indicates the presence of magnetic anisotropy and/or possibly low-lying excited states.

The dynamic magnetic properties of 2 were investigated by ac magnetic susceptibility measurements as a function of temperature at different frequencies and were performed at zero dc field and also under external field of 1000 Oe. The plots of in-phase and out-of-phase ac magnetic susceptibilities at low temperatures under zero dc field are shown in Fig. 6. The data show that the out-of-phase magnetic susceptibility deviates from zero at temperatures below 3 K and at the highest frequencies recorded. The deviation in the values of $\chi^{\prime \prime}$ is frequency dependent and the tails shown are characteristic of slow relaxation of the magnetization. No maximum in $\chi^{\prime \prime}$ is observed down to 2 K , which is the lowest temperature for our setup. Application of a dc field of 1000 Oe did not alter the ac signal profile (Fig. S3). If we assume that the relaxation of the magnetization occurs through a single process, the ac susceptibility data can be approximated with the Debye model with $\ln \left(\chi^{\prime \prime} \mid \chi^{\prime}\right)=\ln \left(\omega \tau_{0}\right)+U_{\text {eff }} / k_{\mathrm{B}} T(\omega=2 \pi v)$ [48] and hence the energy barrier $U_{\text {eff }} / k_{\mathrm{B}}$ and $\tau_{0}$ values can be estimated. The linear fit to the $\ln \left(\chi^{\prime \prime} \mid \chi^{\prime}\right)$ versus $1 / \mathrm{T}$ data gave $U_{\text {eff }} / k_{\mathrm{B}}=9.4 \pm 0.1 \mathrm{~K}$ and preexponential factor $\tau_{0}=1.1 \pm 0.2 \times 10^{-7} \mathrm{~s}$ for 2 (Fig. 7). The plot of $\chi^{\prime \prime}$ versus $\chi^{\prime}$ (Cole-Cole plot) for $\mathbf{2}$ in the temperature range 2.13 K at zero dc field is shown in Fig. 8. The data were simulated according to equation

Fig. 6. Temperature dependence of $\chi^{\prime}$ and $\chi^{\prime \prime}$ of $\mathbf{2}$ under different frequencies at zero external field.

Fig. 7. $\ln \left(\chi^{\prime \prime} \mid \chi^{\prime}\right)$ vs. $1 / \mathrm{T}$ plots for $\mathbf{2}$ in the temperature range $2-3.5 \mathrm{~K}$ at various frequencies. The solid lines represent the fitting results over the temperature range.

Fig. 8. $\chi^{\prime \prime}$ vs. $\chi^{\prime}$ plots for 2 at zero external field. The solid lines represent the simulation semicircles according to Eq. (4).
$\chi^{\prime \prime}=\sqrt{\frac{\left(\chi_{T}-\chi_{S}\right)^{2}}{4}-\left(\chi^{\prime}-\frac{\chi_{S}+\chi_{T}}{2}\right)^{2}}$
where $\chi_{T}$ is the isothermal susceptibility i.e. the susceptibility in zero frequency, and $\chi_{S}$ is the adiabatic susceptibility i.e. the susceptibility at high frequencies where the magnetization is not zero. The solid lines in Fig. 8 represent the simulation semicircles according to Eq. (4) (the respective $\chi_{T}$ and $\chi_{S}$ values at the indicated temperatures are listed in Table S1). The overall magnetic behavior of $\mathbf{2}$ is similar with that of congener $\mathrm{Cu}^{\mathrm{II}}-\mathrm{Tb}^{\mathrm{III}}$ complexes of various topologies and nuclearities which exhibit single-molecule magnet characteristics [33,46b,49-53].

## 4. Concluding comments

The combination of a Schiff base ligand which contains a coordination pocket of $\mathrm{O}_{\text {phenoxo }} / \mathrm{N}_{\text {imino }}$ donor atoms and $\mathrm{O}_{\text {alkoxo }}$ pentant groups with $\mathrm{Cu}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Ln}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Gd}, \mathrm{Tb})$ afforded two heptanuclear heterometallic complexes $\left[\mathrm{Cu}_{5} \mathrm{Ln}_{2}\left(\mathrm{O}_{2}-\right.\right.$
$\left.\mathrm{CMe})_{2}\left(\mathrm{NO}_{3}\right)_{4}(\mathrm{~L})_{2}(\mathrm{HL})_{2}\right](\mathrm{Ln}=\mathrm{Gd}(\mathbf{1}), \mathrm{Tb}(\mathbf{2}))$ whose magnetic properties depend on the nature of the $\mathrm{Ln}^{\text {III }}$ ion. The molecular structure of 1 consists of five $\mathrm{Cu}^{\mathrm{II}}$ and two $\mathrm{Gd}^{\mathrm{III}}$ ions linked through two $\mathrm{L}^{3-}$ and two $\mathrm{HL}^{2-}$ ligands, two $\mu_{3}-\kappa^{3} \mathrm{O}: \kappa^{\prime} \mathrm{MeCO}_{2}^{-}$ligands and four chelate nitrates. The metal topology is best described as two distorted $\left\{\mathrm{Cu}_{3} \mathrm{Gd}\right\}$ cubane subunits with a common apex on a $\mathrm{Cu}^{\text {II }}$ ion. The isomorphous structure of 2 was confirmed by powder XRD measurements. The magnetic susceptibility data for both complexes revealed the presence of dominant ferromagnetic interactions between the metal ions. Magnetization measurements for 1 suggest a ground state of spin $S=17 / 2$ which arises considering that the central $\mathrm{Cu}^{\text {II }}$ ion is antiferromagnetically coupled to the $\mathrm{Cu}_{4} \mathrm{Gs}_{2}$ moiety. The magnetocaloric effect of $\mathbf{1}$, examined by isothermal magnetization studies under $\Delta H=5 \mathrm{~T}$, revealed the maximum entropy change of $15.7 \mathrm{~J} \mathrm{~kg}^{-1} \mathrm{~K}^{-1}$ at 2 K . The significant anisotropy of $\mathrm{Tb}^{\mathrm{III}}$ resulted in single-molecule magnet behavior for $\mathbf{2}$ as shown in ac susceptibility measurements. More work is currently underway in our group to prepare and characterize other members of this family of $\left\{\mathrm{Cu}_{5} \mathrm{Ln}_{2}\right\}$ complexes by varying the lanthanide ions and the Schiff base ligands in order to gain insight into their magnetic properties.
